Let's Start!

What is the Response Object in ASP.NET?

Learning Outcome:

Understand information about web applications, their principles and basic concepts in a range of work contexts. Describe applications for an operating system for personal computers in a range of work contexts.

Can Do Statements:

- I can list some properties of the response object in ASP.NET.
- I can recall some methods of the response object in ASP.NET.
- I can exchange information about properties and methods of the response object in ASP.NET.

Ask your partner:

- How do the server-side controls work?
- Have you ever been transferred to another web page when looking for further information? Why do you think this happens?

Let's Explore!

A web design class is talking about Response Object in ASP.NET.

Instructions: Read the text below.

- Mrs. Adams:** Good morning! Today we are going to talk about the Response Object in ASP.NET. How would you define this type of object?
- Amy:** Well... Response Object in ASP.NET is understood as the server's response or output sent to the client request. Even if this object is not vital for page processing, it still offers different functionalities that are important when sending output. For example, it provides cookie features to set cookie values, and it uses the Redirect Method that can transfer a client to other URL.
- Mrs. Adams:** That's right, Amy. You should also bear in mind that Response.Redirect performs a round trip when executing. What are other methods of the Response Object?
- Eddie:** Regarding methods, there is one called AppendToLog; it is used to add strings to entries at the end of the Web server log.
We also have the AppendCookie, which is understood as a method that adds HTTP cookies to the inherent cookie collection. Finally, it is also possible to mention BinaryWrite, which is in charge of writing a series of binary characters to the HTTP output flow.
- Mrs. Adams:** I would add some more. We can mention, for instance, Clear content, which deletes all buffered HTML output; End, which interrupts processing files to rise an EndRequest event; and Flush, which allows sending buffered output directly, among others. As you may know, the Response Object is composed of some properties too; which ones do you recall?
- Amy:** By way of example, we could name CacheControl; it specifies a header to declare if the proxy server is able to cache the output that is produced or not. There also is ContentType. It sets the HTTP content type to send. LCID defines aspects such as dates, time, and currency according to a specific geographical position.
- Eddie:** Do not forget about Status; the status line that is returned to the client machine is defined by this property.

Let's Practice!

The Response Object is composed of some properties too; which ones do you recall?

Instructions: Move the words from the box to correctly complete the sentences.

is produced or not / is set by / are declared by /
is understood as / is returned to

1. The Response Object in ASP.NET _____ the server's response or output sent to the client request.
2. We could name CacheControl; it specifies a header to declare if the proxy server is able to cache the output that _____.
3. The HTTP content type to send _____ ContentType.
4. Aspects, such as dates, time, and currency _____ LCID according to a specific geographical position.
5. Do not forget about Status; the status line that _____ the client machine is defined by this property.

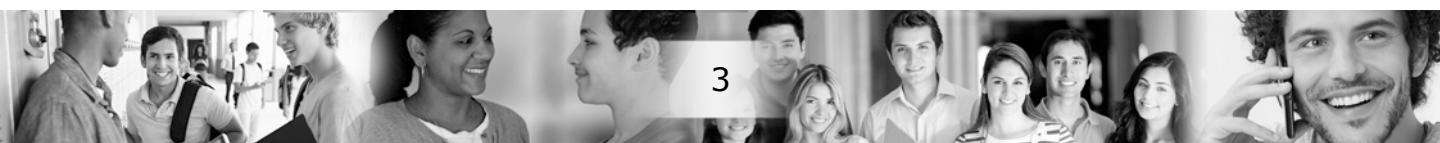

Let's Practice!

What are other methods of the Response Object?

Instructions: Read the question. Select all the correct answers.

1. Which of these sentences about methods of the Response Object are true?
 - a. AppendToLog provides cookie features to set cookie values.
 - b. Clear content deletes all buffered HTML output.
 - c. AppendCookie adds HTTP cookies to the inherent cookie collection.
 - d. BinaryWrite can transfer a client to other URL.
 - e. Flush allows sending buffered output directly.

Extension Activity

Mind Mapping about Properties and Methods of the Response Object.

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Look for more information about properties and methods of the Response Object in ASP.NET.
- Identify the main features of each property and method.
- Create a mind map to summarize the main features of a group of properties and methods of the Response Object.
- Prepare an oral presentation to explain your mind map.
- Share your work with the class.

Self-Assessment

Yes No

- I look for more information about properties of methods of the Response Object in ASP.NET.
- I identify the main features of each property and method.
- I create a mind map to summarize the main features of a group of properties and methods of the Response Object.
- I prepare an oral presentation to explain my mind map.
- I share my work with the class.

Target Words

- buffered** (adjective): when something is collected
e.g. We can mention, for instance, Clear content, which deletes all buffered HTML output.
- proxy server** (noun): a computer system that intercepts all the requests sent from other servers
e.g. It specifies a header to declare if the proxy server is able to cache the output that is produced or not.
- cache** (verb): to save data for temporary storage
e.g. It specifies a header to declare if the proxy server is able to cache the output that is produced or not.
- round trip** (noun): an event that requires to go to the server and then return back to the server to complete a request
e.g. You should also bear in mind that Response.Redirect performs a round trip when executing.
- string** (noun): a class that symbolizes pieces of text in a sequence
e.g. it is used to add strings to entries at the end of the Web server log.
- web server log** (verb): a file that records all the actions performed by the server
e.g. it is used to add strings to entries at the end of the Web server log.

Learning Points

Simple Present Passive

We use sentences in **simple present passive** or **present passive voice** when we want to stand out the function of an **object** in a sentence rather than the **subject**. This tense is commonly used when we expect to provide explanations.

When we aim to highlight the person or element that performs an action, we use *active voice*:

- **ASP.NET** processes pages and it produces a dynamic output to specify the life cycle.

But when it comes to highlight the role of the object in a sentence, we need to use the passive voice:

- **Pages** are processed to specify the life cycle.
- **Pages** are processed by ASP.NET to specify the life cycle.

When using the passive voice the subject could be omitted, but in case you wish to mention it, you need to use the particle **by** followed by the noun.

This is the grammatical structure we need to use when building sentences in **simple present passive**:

Object + Verb be + Verb in past participle + Complement

For example:

*The AddHeader **is understood** as a method that adds an HTTP header to the output stream.*

Examples

- *Response Object in ASP.NET is understood as the server's response or output sent to the client request.*
- *As you may know, the Response Object is composed of some properties too; which ones do you recall?*
- *The AppendCookie is understood as a method that adds an HTTP cookie to the intrinsic cookie collection.*

Learning Points

Properties in the Response Object in ASP.NET

The **Response Object** is in charge of sending output content from the server to the user in ASP.NET; in order to accomplish this, different properties are set when coding a page or application in this framework.

The chart below presents some of the most common **properties** that can be defined by the **Response Object** in ASP.NET:

Property	Description
Buffer	Sets values to specify if an output should be buffered or not and it is also in charge of sending the response when processing is done.
Cache Control	Defines if the output produced by ASP can be cached by a proxy server or not.
Charset	Attaches the HTTP character set in the Response Object.
ContentType	Sets the HTTP MIME type of the output object.
Expires	Specifies the length of time required before a page cached on a browser expires.
Headers	Takes the collection of response headers.
IsClientConnected	Specifies whether the client disconnects or not from the server.
RedirectLocation	Defines the values of the HTTP location header.
SuppressContent	Sets a value specifying if it is possible to send HTTP content to the client or not.
