Let's Start!

Access Database.

Learning Outcome:

Understand information about web applications, their principles and basic concepts in a range of work contexts. Describe applications for an operating system for personal computers in a range of work contexts.

Can Do Statements:

- I can understand written information about database access in ASP.NET.
- I can use vocabulary about database access in ASP.NET.
- I can write a descriptive text about database access in ASP.NET.

Ask your partner:

- What technology do you think it is necessary to control objects in databases? Why are they necessary?
- Do you think it is important to manipulate data and databases?

Let's Explore!

George is regretting about how we controlled data and data access.

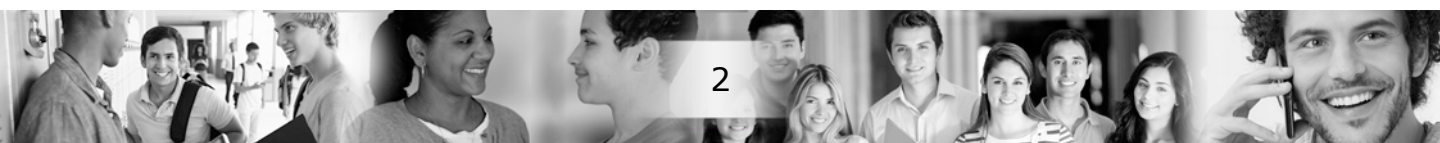

Instructions: Read the text below.

Good morning guys, today I am going to share with all of you, my testimony when I was working with database access. Unfortunately, I didn't have someone who advises me as I am doing right now, and of course, if I had an advisor I would teach him because I am pretty sure that I have more experience than any other. In my hands, I have a descriptive text of my stories which you can acquire at the end of this speech.

So basically, there is a new technology that allows us to access to database sources, if you knew sources which provide access to XML documents, you would have better organization of data in programming objects and if you had flat files with complex processes, then you would need to find someone who helps you to control programming classes and objects.

Now, ASP.NET makes our lives easier; ASP.NET control objects and the backend data source which hide complex coding for connection, data retrieving, data querying, and data manipulation. If I used two types of data controls, I would retrieve and display data in ASP.NET: data source control and data view control. For instance, Data Source Control which manages the connection, selection, modification of data and even paging and caching that refers to the organization of data and if I used data view control, I would manipulate data. And of course, if I followed data binding process, I would notice data changes immediately. As you see it is necessary to have equilibrium so that you can use ASP.Net as a tool to have a snapshot of all the information needed in an organized way.

Let's Practice!

ASP.NET useful information.

Instructions: Read the statement. Select all the correct answers.

1. What are ASP.NET main functions?
 - a. ASP.NET allows users to browse the internet.
 - b. ASP.NET allows data to be accessed and used from Access, SQL Server, Oracle, MySQL.
 - c. ASP.NET controls objects and the backend data source.
 - d. ASP.NET writes code for applications.
 - e. ASP.NET provides much higher level of classes and objects.

Let's Practice!

What is ASP.NET?

Instructions: Match the sentences from Column A with Column B.

COLUMN A

1. ASP.NET is a source that
2. ASP.NET is a source which
3. ASP.NET is a technology which
4. These types of data controls which
5. ASP.NET is a technology which

COLUMN B

- a. takes two types of data controls to retrieve and display data.
- b. ASP.NET needs are data source control and data view control.
- c. hides complex coding for connection, data retrieving, data querying, and data manipulation.
- d. can access and use Flat files.
- e. can access XML documents.

Extension Activity

More examples of database access.

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Investigate about another database access engine similar to ASP.NET.
- Write your findings, advantages and disadvantages of this database access engine.
- Create a presentation with the advantages and disadvantages of this database access engine.
- Share it with your teacher and classmates.

Self-Assessment

- I read about database access engines like ASP.NET.
- I write about database access in ASP.NET and other engines.
- I create a presentation with the advantages and disadvantages of this database access engine.
- I share it with your teacher and classmates.

Target Words

- XML document** (noun): Extensible Markup Language, language that encode a document in a specific format e.g. if you knew sources which provide access to XML documents, you would have better organization of data in programming objects
- flat files** (noun): database which store internal information e.g. (...) if you had flat files with complex processes, then you would need to find someone who helps you to control programming classes and objects.
- backend** (noun): database you can access from an application e.g. Now, ASP.NET makes our lives easier; ASP.NET controls objects and the backend data source which hide complex coding for connection, data retrieving, data querying, and data manipulation.
- data querying** (noun): process of asking questions about data e.g. Now, ASP.NET makes our lives easier; ASP.NET controls objects and the backend data source which hide complex coding for connection, data retrieving, data querying, and data manipulation.
- data binding** (noun): process that establish a connection between settings and data notification e.g. And of course, if I followed data binding process, I would notice data changes immediately.
- snapshot** (noun): representation of a specific condition in time e.g. As you see it is necessary to have equilibrium so that you can use ASP.Net as a tool to have a snapshot of all the information needed in an organized way.

Learning Points

Subject and Object Relative Clauses

You use relative clauses to give more information about what we are talking about, so that it can be clear.

Within relative clauses, there are **subject** and **object relative clauses**.

You use relative pronouns to give more information about what you're talking about. Those relative pronouns are: who – which – that.

Relative clauses- Subject

You use them to clarify something and you use them after the subject.

Example:

- *I was looking for the programmer **who** can control databases well.*
- *She was looking for someone **that** can help her.*

Relative clauses- Object

You use them to clarify something or to give extra information about objects or situations.

Example:

- *Kevin deals with databases **which** are hard to control.*
- *Kevin work on database **that** are tough to control.*

Examples

- *Unfortunately, I didn't have someone who advises me as I am doing right now.*
- *Data Source Control which manages the connection, selection, modification of data and even paging and caching that refers to the organization of data.*

Learning Points

Unreal Conditional Sentences

You use **unreal conditional sentences** to describe actions that are not probably going to be true in the future. It is known as the **second conditional**.

In English you use the **second conditional** to speak about present and future situations which are unlikely to happen.

This **second conditional** follows a specific grammatical structure using simple past and would.

If + Conditional sentence in Past Simple + Result with Would * infinitive.

Structure:

If	Past Simple	Would + infinitive
<i>If I</i>	<i>controlled data</i>	<i>I would invent a new technological tool to access to it.</i>
<i>If she</i>	<i>had an idea</i>	<i>She would share it with us.</i>

Examples

- *If I had an advisor I would teach him because I am pretty sure that I have more experience than any other.*
- *If you knew sources which provide access to XML documents, you would have better organization of data in programming objects.*
- *If I used data view control, I would manipulate data.*
